Abstract A new feed topology is presented that potentially can open new solutions for covering the new VGOS configuration and its associated frequency bands. In this approach a single band from 2 to 14 GHz is considered. A log-spiral antenna is printed on a conic surface. The whole structure is adjusted in order to obtain a pure circular polarization at broadside direction. An array of four elements is proposed for obtaining a dual-circular polarization feed. Simulations show an efficiency higher than 70% on a ring focus radio telescope illuminated with this feed.

Keywords VGOS, radio telescope, ring focus, broadband feed

1 The RAEGE Ring Focus Radio Telescope

The RAEGE radio telescope optical system is shown in Figure 1. It is composed of one main parabolic mirror and an elliptical subreflector. The entire system has rotational symmetry. The diameter of the main (Dm) and secondary (ds) mirrors are 13.2 m and 1.55 m, respectively. The distance between the highest focal point of the elliptical mirror and the vertex of the parabola (fp) is 3.7 m. The feed is placed into a cryostat below the subreflector.

The optimum performance of this system is obtained with an ideal Gaussian feed placed in the focus of the subreflector, using a taper of −16 dB. GRASP tool has been used for analyzing the complete system. Figure 2 shows the maximum efficiency which goes from 72% to 81%. The sidelobe level is −13 dB and the antenna temperature goes from 30 to 2 Kelvin (Figure 3).

2 The DYQSA Feed

The geometry proposed for the feed is based on a conical, log-spiral antenna (Dyson 1962, 1965). This is the origin of the name for the solution we have selected, devoted to the impressive work on this kind of antennas by Professor Dyson.

The antenna configuration is shown in Table 1. The full feed, based on the conical log-spiral antenna (see Figure 4), uses four units (Figure 5).

Two antennas are devoted to one polarization (RHCP), while the other two antennas are devoted to the opposite one (LHCP). The angle between the axis of the cones and the z-axis is 16°. The radiation pattern of the antenna (Figure 6) was analyzed using the CST, Microwave Studio, and HFSS Ansoft softwares, obtaining the same results for both systems.

The phase center changes by 6 cm over the whole band (Figure 7). However, the variation is only 2 cm between 4 and 14 GHz. This will cause a reduction in efficiency for a fixed position of the antenna. However, this efficiency can be optimized to be always above 60% for different fixed positions of the feed from the focus, as is shown in Figure 9.
3 First Measurements

A titanium first prototype of the feed single element has already been built (to assure no deformation of the feed). The measurements were done at the Yebes anechoic chamber and they show very good agreement with theory. Simulations with GRASP show that placing this feed at the focus of the system can reach efficiencies higher than 70% in the whole band.

4 Conclusions

A totally novel antenna topology for covering the requirements of the VGOS system has been presented. The DYQSA antenna is a new solution for broadband ring focus feeds. It offers simultaneous dual-circular polarization over the whole band of 2–14 GHz. The simulated efficiency of the ring focus using this feed is approximately 70%. The DYQSA feed is similar in
volume to the QFH feed. An already built prototype shows good agreement with theory. A final prototype will be finished in 2015.
